Potential Natural Vegetation Group (PNVG):

Rapid Assessment Reference Condition Model

The Rapid Assessment is a component of the LANDFIRE project. Reference condition models for the Rapid Assessment were created through a series of expert workshops and a peer-review process in 2004-2005. For more information, please visit www.landfire.gov. Please direct questions to helpdesk@landfire.gov.

Geographic Range

This forest type occurs in southwest Oregon, up to and just barely over the Cascades Range. It likely can be used in parts of Northern California.

Biophysical Site Description

High elevation (4,000 to 6,900 ft) species in southern Oregon Cascades. Cool moist to cold moist microclimate. 30-50 in precipitation. Highly variable geology.

Vegetation Description

Red fir in the late seral stage often occurs with white fir at lower elevations and mountain hemlock at higher elevations. Other common associates include Douglas-fir, western white pine, and lodgepole pine (on wet sites).

Red fir occurs on pumice in the high Cascades. Separate red fir community in the Siskiyous.

Disturbance Description

Mixed severity fires are the most common disturbance, but windthrow and dwarf mistletoe can be major disturbance agents, too.

Adjacency or Identification Concerns

Northern variant of California red fir. Relied heavily on the red fir model developed for the FRCC Guidebook by Ayn Shlisky (RFCA).

Replaced by white fir (mixed conifer) at lower elevations and mountain hemlock at higher elevations.

This PNVG may be similar to the PNVGs R1RFWP and R1RFWF for the California Model Zone. Where

*Dominant and Indicator Species are from the NRCS PLANTS database. To check a species code, please visit http://plants.usda.gov.
California Red fir (Abies magnifica var. magnifica) is present, consult these two PN VGs.

**Scale Description**

The mosaic of the forest type is dominated by mixed severity events, each event encompassing 1000s of acres.

**Issues/Problems**

Two types occur: 1) Cascade type: Pumice soils. Conifers are red fir, mountain hemlock, lodgepole pine and white pine. Occurs between mountain hemlock and white fir zones. Cascade stands are more open. Red fir averages 25-35% cover in late seral stages.

2) Siskiyou type: Granitic soils. Conifers are red fir, white fir, Douglas-fir. Occurs between mountain hemlock and white fir zones. Red fir averages 30-50% cover in late seral stages.

**Model Evolution and Comments**

Review included one anonymous reviewer.

One reviewer suggested to clearly indicate the differences between California red fir and Shasta red fir models.

Three of four reviewers felt that the frequency of fire was too high. Cope (1993) indicates that Shasta red fir (A. magnifica var. shastensis) has MFRI 70-130 years, and can withstand surface fires, whereas California red fir (A. magnifica var. magnifica) has a return of 10-65 years. In addition, Jim Merzenich had comments on structural inconsistencies in the model. John Foster adjusted the model by using regime parameters derived from the original model, but adjusted to reflect Cope (1993) and research in the Oregon Cascades.

### Succession Classes

*Succession classes are the equivalent of "Vegetation Fuel Classes" as defined in the Interagency FRCC Guidebook (www.frcc.gov).*

**Fire Intervals (FI):**
Fire interval is expressed in years for each fire severity class and for all types of fire combined (All Fires). Average FI is the central tendency modeled. Minimum and maximum show the relative range of fire intervals, if known. Probability is the inverse of fire interval in years and is used in reference condition modeling. Percent of all fires is the percent of all fires in that severity class. All values are estimates and not precise.
